CHAPTER ONE

INTRODUCTION

1.0 Overview

Urban communities increasingly face diverse incidents such as crime, infrastructure faults, fire outbreaks, and road accidents. Traditional, paper-based or face-to-face incident reporting is often slow, fragmented, and lacks precise location information, which delays response and weakens accountability (Zengeya et al., 2023). At the same time, the widespread adoption of smartphones, mobile internet, and GPS has created opportunities for citizen-centric, geotagged incident reporting platforms that can support faster, more transparent public service delivery (Bulusan et al., 2019; Nuevas et al., 2024). Geospatial technologies, particularly Geographic Information Systems (GIS), web mapping APIs, and spatial analysis tools enable communities and authorities to visualize incidents on digital maps, identify hotspots, and coordinate responses more effectively (Fitriani et al., 2019; Bhanumurthy et al., 2015). Community-based incident reporting and mapping systems have been shown to improve awareness, collaboration between citizens and government agencies, and data-driven decision-making in emergency management and urban governance (Augustus et al., 2018; Kassab et al., 2010; Kawasaki et al., 2013). This study focuses on the design and development of a community incident reporting system that leverages geospatial technology to capture, store, visualize, and manage incident data. By integrating mobile and web technologies with mapping services, the system aims to provide a unified platform through which residents can report incidents and authorities can monitor and respond in near real time.

1.1 Background of the Study

An essential part of contemporary urban governance and emergency management is effective incident reporting. However, reporting procedures are still informal in many places, depending on walk-in complaints, phone calls, or social media posts that are not spatially explicit, standardized, or verifiable (Arispe, 2020; Zengeya et al., 2023). Authorities find it challenging to assign resources, prioritize occurrences, and examine risk trends in space when using such methods. Digital, geotagged event reporting platforms can close this gap, according to recent research. Authorities may display event markers, verify reports, and provide pertinent information to the public using community-based incident reporting and mapping systems that use Google Maps and reverse geocoding (Augustus et al., 2018). Mobile applications for incident reporting using GPS have been found to reduce errors in location reporting and support more accurate and rapid emergency response (Bulusan et al., 2019; Nuevas et al., 2024). Similarly, web-GIS incident management systems have improved situational awareness and coordination for traffic accidents and fire incidents through spatial visualization and route optimization (Arispe, 2020; Fitriani et al., 2019; Anuar et al., 2025). Beyond individual use cases, geospatial technologies are increasingly recognized as foundational for emergency management frameworks, supporting damage assessment, situation monitoring, information dissemination, and resource coordination (Bhanumurthy et al., 2015; Kawasaki et al., 2013). Community-level platforms that enable residents to submit geotagged reports and visualize hazards can enhance resilience by strengthening the “information chain” between citizens and public safety officials (Hosseini Shakib et al., 2025; Apostol et al., 2023). Despite these advances, many communities still lack an integrated, user-friendly system that allows residents to report a broad range of local incidents and enables authorities to manage them through geospatial visualization and analysis. This study is

motivated by the need to adapt and extend these concepts into a context-appropriate community incident reporting system using geospatial technology.

1.2 Problem Statement

In the target community, incident reporting is largely manual and fragmented. Residents typically report issues such as broken public infrastructure, minor crimes, environmental hazards, or fire risks through informal channels, including verbal complaints, phone calls, or unstructured social media posts. These mechanisms suffer from several limitations:

1. **Lack of precise location information:** Descriptions of incident locations are frequently vague or ambiguous, making it difficult for authorities to quickly identify and access the affected site (Bulusan et al., 2019; Arispe, 2020).
2. **Delayed and inconsistent reporting:** Reliance on in-person or phone-based reporting often leads to delays, missed incidents, or incomplete documentation, resulting in slower response times (Nuevas et al., 2024; Zengeya et al., 2023).
3. **Absence of centralized, geospatially enabled records:** Incident data, where recorded, are often stored in spreadsheets or paper files without map-based visualization or analytical tools, limiting the ability to detect hotspots, recurring patterns, or trends (Fitriani et al., 2019; Rodrigo & Jayasinghe, 2025).
4. **Limited citizen feedback and transparency:** Residents usually have no way to track the status of their reports or view incident distributions in their area, reducing trust and community engagement (Augustus et al., 2018; Anuar et al., 2025).

Existing research and implementations show that geospatially enabled incident reporting and mapping systems can significantly improve notification rates, response coordination, and

data-driven planning (Augustus et al., 2018; Arispe, 2020; Kassab et al., 2010; Zengeya et al., 2023). However, there is no locally tailored system that integrates mobile reporting, geotagging, mapping, and basic analytics for general community incidents in the study area.

Therefore, the problem this research addresses is the lack of an integrated, geospatially enabled community incident reporting system that allows residents to submit geotagged incident reports and enables authorities to visualize, monitor, and manage these incidents efficiently.

1.3 Research Aims and Objectives

1.3.1 Aim

The main aim of this study is to design and develop a community incident reporting system that utilizes geospatial technology to support efficient reporting, visualization, and management of incidents within the community.

1.3.2 Objectives

The specific objectives of the study are to:

1. Analyze the existing processes and challenges associated with community incident reporting and management in the study area.
2. Design a system architecture and data model for a community incident reporting platform that integrates geospatial components such as GPS, mapping APIs, and spatial data storage (Augustus et al., 2018; Kawasaki et al., 2013).
3. Develop a prototype web application that enables residents to submit geotagged incident reports with relevant attributes and enables authorized officials to view and manage these

incidents on an interactive map (Bulusan et al., 2019; Nuevas et al., 2024; Zengeya et al., 2023).

4. Implement map-based visualization and basic spatial analysis features (e.g., incident clustering, hotspot identification) to support monitoring and decision-making (Fitriani et al., 2019; Arispe, 2020; Rodrigo & Jayasinghe, 2025).
5. Evaluate the usability and perceived usefulness of the developed system among selected community members and relevant authorities.

1.4 Significance of the Study

The study is expected to contribute in several ways:

- **For local authorities and emergency services:** the system will provide a centralized, geospatially enabled platform for receiving, viewing, and managing incident reports. Prior work indicates that such platforms can reduce response times, improve situational awareness, and support more effective allocation of resources (Kassab et al., 2010; Arispe, 2020; Nuevas et al., 2024; Anuar et al., 2025).
- **For community members:** residents will gain an accessible channel to submit geotagged reports and track incident status, fostering transparency and engagement. Community-based reporting systems have been shown to enhance public awareness and collective responsibility for local safety and infrastructure (Augustus et al., 2018; Zengeya et al., 2023; Pranay et al., 2025).
- **For planners and policymakers:** the geospatial database produced by the system will support evidence-based planning by revealing spatial patterns, hotspots, and trends in

incidents over time (Fitriani et al., 2019; Kawasaki et al., 2013; Rodrigo & Jayasinghe, 2025). This can inform preventive interventions and long-term investments.

- **For academic and technical communities:** the research will add to the growing body of work on integrating geospatial technologies, web/mobile development, and citizen participation for incident and disaster management (Bhanumurthy et al., 2015; Hosseini Shakib et al., 2025; Apostol et al., 2023). The system design, implementation approach, and evaluation results may serve as a reference for similar initiatives in other communities.

Overall, the study aligns with broader trends toward digital, data-driven, and participatory governance in managing urban risks and public services.

1.5 Scope and Limitations of the Research Work

1.5.1 Scope

The study is limited to the design and development of a prototype community incident reporting system using geospatial technology. Specifically:

- The system will focus on selected categories of community incidents (e.g., infrastructure faults, environmental hazards, minor safety issues), which will be defined in consultation with local stakeholders.
- The prototype will include core functionalities such as user registration/authentication, geotagged incident submission, map-based visualization of incidents, basic filtering, and simple status tracking, consistent with features described in related systems (Augustus et al., 2018; Zengeya et al., 2023; Anuar et al., 2025).

- The geospatial component will rely on widely used mapping platforms and APIs (e.g., Google Maps or similar web-GIS frameworks) and store spatial data in a relational or spatially enabled database (Augustus et al., 2018; Kassab et al., 2010).
- Evaluation will be conducted with a limited number of users (e.g., selected residents and officials) using usability and acceptance measures, as applied in comparable studies (Bulusan et al., 2019; Arispe, 2020; Nuevas et al., 2024).

1.5.2 Limitations

The research has several limitations:

1. **Prototype nature:** The system developed is a prototype and may not include all functionalities required for full-scale deployment, such as comprehensive security hardening, multilingual interfaces, or integration with legacy government systems.
2. **Data coverage and reliability:** Incident data used during testing and evaluation will depend on voluntary participation and may not represent all incidents in the community, similar to constraints observed in other community-based systems (Apostol et al., 2023; Zengeya et al., 2023).
3. **Technical and infrastructure constraints**: The performance and usability of the system may be affected by device capabilities, network connectivity, and the quality of base map data, as noted in other geospatial and mobile emergency systems (Fitriani et al., 2019; Sammadile et al., 2025).
4. **Organizational and policy factors:** The study does not fully address organizational change management, long-term maintenance, or formal policy integration, which are often

critical for sustainable adoption of geospatial platforms in public institutions (Bhanumurthy et al., 2015; Kawasaki et al., 2013).

These limitations will be considered when interpreting the findings and making recommendations for future work.

1.6 Organization of the Study

The project has been organized into the following chapters:

Chapter 1: Introduction

Provides an overview of the study, including the background, problem statement, research objectives, significance of the study, and the organization of the entire report.

Chapter Two: Literature Review

Presents a review of related literature on community incident reporting, geospatial technologies, web and mobile-based emergency systems, and frameworks for integrating GIS into emergency and urban management.

Chapter Three: System Specification and Design

Describes the research methodology, including system requirements analysis, design methodology, development tools, and evaluation methods.

Chapter Four: System Implementation

Details the system design and implementation, covering the architecture, database schema, user interfaces, and geospatial components. It also presents the results of system testing and user evaluation, analyzing usability, performance, and perceived usefulness.

Chapter Five: Conclusion and Recommendation

Provides the summary of the key findings and achievements of the study, discusses challenges encountered, and suggests possible future improvements to enhance the system.
